General Microbiology Linda Bruslind,2020 Welcome to the wonderful world of microbiology Yay So What is microbiology If we break the word down it translates to the study of small life where the small life refers to microorganisms or microbes But who are the microbes And how small are they Generally microbes can be divided in to two categories the cellular microbes or organisms and the acellular microbes or agents In the cellular camp we have the bacteria the archaea the fungi and the protists a bit of a grab bag composed of algae protozoa slime molds and water molds Cellular microbes can be either unicellular where one cell is the entire organism or multicellular where hundreds thousands or even billions of cells can make up the entire organism In the acellular camp we have the viruses and other infectious agents such as prions and viroids In this textbook the focus will be on the bacteria and archaea traditionally known as the prokaryotes and the viruses and other acellular agents

Bacterial Cell Wall Structure and Dynamics Tobias Dörr, Partick J. Moynihan, Christoph Mayer, 2019-12-27 Bacterial cells are encased in a cell wall which is required to maintain cell shape and to confer physical strength to the cell. The cell wall allows bacteria to cope with osmotic and environmental challenges and to secure cell integrity during all stages of bacterial growth and propagation and thus has to be sufficiently rigid. Moreover, to accommodate growth processes, the cell wall at the same time has to be a highly dynamic structure. During cell enlargement, division, and differentiation, bacteria continuously remodel, degrade, and resynthesize their cell wall but pivotally need to assure cell integrity during these processes. Finally, the cell wall is also adjusted according to both environmental constraints and metabolic requirements. However, how exactly this is achieved is not fully understood. The major structural component of the bacterial cell wall is peptidoglycan (PG), a mesh-like polymer of glycan chains interlinked by short chain peptides, constituting a net-like macromolecular structure that has historically also been termed murein or murein sacculus. Although the basic structure of PG is conserved among bacteria, considerable variations occur regarding cross-bridging modifications and attachments. Moreover, different structural arrangements of the cell envelope exist within bacteria: a thin PG layer sandwiched between an inner and outer membrane is present in Gram-negative bacteria, and a thick PG layer decorated with secondary glycopolymers, including teichoic acids, is present in Gram-positive bacteria. Furthermore, even more complex envelope structures exist, such as those found in mycobacteria. Crucially, all bacteria possess a multitude of often redundant lytic enzymes termed autolysins and other cell wall modifying and synthesizing enzymes, allowing to degrade and rebuild the various structures covering the cells. However, how cell wall turnover and cell wall biosynthesis are coordinated during different stages of bacterial growth is currently unclear. The mechanisms that prevent cell lysis during these processes are also unclear. This Research Topic focuses on the dynamics of the bacterial cell wall, its modifications, and structural rearrangements during cell growth and differentiation. It pays particular attention to the turnover of PG, its breakdown, and recycling, as well as the regulation of these processes. Other structures, for example secondary polymers such as teichoic acids, which are dynamically changed during bacterial growth and differentiation, are also covered. In recent years, our view on the bacterial cell envelope has undergone a dramatic change that challenged old models of cell wall structure, biosynthesis, and turnover. This collection of articles aims to contribute to new understandings of bacterial cell wall structure and dynamics.
